

AMENDMENTS TO THE CLAIMS

1. (Currently Amended) A phase adjusting circuit for generating a phase adjusting value based on the phase difference of a target clock signal and an input signal, the phase adjusting circuit comprising:

a phase-frequency detector for generating a first control signal and a second control signal by comparing the phase of the input signal with the phase of the target clock signal;

a clock generator for generating a reference clock;

a counter connected to the phase-frequency detector and the counter for generating a first counting value by counting the number of cycles of the reference clock during the duration of the first control signal, and generating a second counting value by counting the number of cycles of the reference clock during the duration of the second control signal; and

a decision logic circuit connected to the counter for generating a third counting value based on the first counting value and the second counting value, calculating the sum of a plurality of the third counting values, setting the phase adjusting value to zero if the sum is within a specified range, and setting the phase adjusting value according to the sum if the sum is outside the specified range ~~and comparing the sum with a predetermined range for outputting the phase adjusting value as the counting times are increased to equal to a predetermined counting times.~~

2. (Original) The phase adjusting circuit of claim 1, wherein the first control signal is generated when the phase of the input signal leads the phase of the target clock signal.

3. (Original) The phase adjusting circuit of claim 1, wherein the second control signal is generated when the phase of the input signal lags the phase of the target clock signal.

4. (Currently Amended) The phase adjusting circuit of claim 1, wherein the reference clock frequency is N times the frequency of the target clock signal and the predetermined—specified range ranges from a positive number of ~~a half of the predetermined counting times~~ N/2 to a negative number having an absolute value of ~~a half of the predetermined counting times~~ N/2.

5. (Original) The phase adjusting circuit of claim 1, wherein the first counting value is a positive value, the second counting value is a negative value, and the third counting value is the sum of the first counting value and the second counting value.

6. (Original) The phase adjusting circuit of claim 1, wherein the phase-frequency detector is further able to receive a protection signal to stop outputting the phase adjusting value for avoiding interference generated from an unstable input signal.

7. (Currently Amended) A clock signal adjusting circuit comprising:
a phase adjusting circuit for generating a phase adjusting value based on an input signal and a target clock signal, the ~~phase—phase~~ phase adjusting circuit comprising:
a phase-frequency detector for generating a first control signal and a second control signal by comparing the phase of the input signal with the phase of the target clock signal;
a clock generator for generating a second reference clock;
a counter connected to the phase-frequency detector and the clock generator for generating a first counting value by counting the number of cycles

of the second reference clock during the duration of the first control signal, and generating a second counting value by counting the number of cycles of the second reference clock during the duration of the second control signal; and

a decision logic circuit connected to the counter for generating a third counting value based on the first counting value and the second counting value, calculating the sum of a plurality of the third counting values, setting the phase adjusting value to zero if the sum is within a specified range, and setting the phase adjusting value according to the sum if the sum is outside the specified range ~~and comparing the sum with a predetermined range for outputting the phase adjusting value as the counting times are increased to equal to a predetermined counting times; and~~

a frequency divider connected to the phase adjusting circuit for adjusting the target clock signal by dividing the frequency of a first reference clock based on the phase adjusting value.

8. (Cancelled)

9. (Previously Presented) The clock signal adjusting circuit of claim 7, wherein the first control signal is generated when the phase of the input signal leads the phase of the target clock signal.

10. (Previously Presented) The clock signal adjusting circuit of claim 7, wherein the second control signal is generated when the phase of the input signal lags the phase of the target clock signal.

11. (Currently Amended) The clock signal adjusting circuit of claim 7, wherein the second reference clock frequency is N times the frequency of the target clock signal and the predetermined-specified range ranges from a positive number of a half of the predetermined-counting-times-N/2 to a negative number having an absolute value of a half of the predetermined-counting-timesN/2.

12. (Currently Amended) The clock signal adjusting circuit of claim 7, wherein the frequency divider comprises:

- a counter for counting the cycle number of cycles of the first reference clock and resetting the cycle number after ~~each predetermined~~ a specified number of cycles of the first reference clock;
- a register for storing the phase adjusting value;
- a comparator connected to the counter and the register for generating an enable signal when the cycle number of the first reference clock is equal to the phase adjusting value;
- a pulse generator connected to the comparator for generating an impulse when receiving the enable signal;
- a flip-flop having a trigger input terminal connected to the pulse generator for outputting the target clock signal while receiving the impulse; and
- an inverter having an input terminal for receiving the target clock signal and inverting the target clock signal to feedback to the input of the flip-flop.

13. (Original) The clock signal adjusting circuit of claim 7 being applied to an optical disc drive, the input signal being a wobble signal of an optical disc, the target clock signal being a corresponding wobble clock generated by the optical disc drive based on the wobble signal.

14. (Currently Amended) A method for adjusting clock signal comprising:

~~generating a phase adjusting value based on an input signal and a target clock signal;~~
generating a first control signal and a second control signal by comparing the phase of ~~the~~ an input signal with the phase of ~~the~~ a target clock signal;
generating a first counting value by counting the number of cycles of a second reference clock during the duration of the first control signal;
generating a second counting value by counting the number of cycles of the second reference clock during the duration of the second control signal;
generating a third counting value based on the first counting value and the second counting value;
calculating the sum of a plurality of the third counting values; and
~~comparing the sum with a predetermined range for outputting the phase adjusting value as the counting times are increased to equal to a predetermined counting times; and~~ setting a phase adjusting value to zero if the sum is within a specified range and setting the phase adjusting value according to the sum if the sum is outside the specified range; and
adjusting the target clock signal by dividing the frequency of a first reference clock based on the phase adjusting value.

15. (Cancelled)

16. (Previously Presented) The method of claim 14, wherein the first control signal is generated when the phase of the input signal leads the phase of the target clock signal.

17. (Previously Presented) The method of claim 14, wherein the second control signal is generated when the phase of the input signal lags the phase of the target clock signal.

18. (Currently Amended) The method of claim 14, wherein the the second reference clock frequency is N times the frequency of the target clock signal and the predetermined specified range ranges from a positive number of ~~a half of the predetermined counting times~~ $N/2$ to a negative number having an absolute value of ~~a half of the predetermined counting times~~ $N/2$.

19. (Original) The method of claim 14 further comprising:
counting the cycle number of cycles of the first reference clock and resetting the cycle number after each predetermined number of cycles of the first reference clock;
generating an enable signal when the cycle number of the first reference clock is equal to the phase adjusting value;
generating an impulse when receiving the enable signal;
outputting the target clock signal while receiving the impulse; and
inverting the target clock signal to feedback to the input.

20. (Original) The method of claim 14 being applied to an optical disc drive, the input signal being a wobble signal of an optical disc, the target clock signal being a corresponding wobble clock generated by the optical disc drive based on the wobble signal.

21. (New) An apparatus for adjusting a clock signal comprising:
means for generating a first control signal and a second control signal by comparing the phase of an input signal with the phase of a target clock signal;
means for generating a first counting value by counting the number of cycles of a second reference clock during the duration of the first control signal;
means for generating a second counting value by counting the number of cycles of the second reference clock during the duration of the second control signal;

means for generating a third counting value based on the first counting value and the second counting value;
means for calculating the sum of a plurality of the third counting values;
means for setting a phase adjusting value to zero if the sum is within a specified range and setting the phase adjusting value according to the sum if the sum is outside the specified range; and
means for adjusting the target clock signal by dividing the frequency of a first reference clock based on the phase adjusting value.

22. (New) The apparatus of claim 21, wherein the first control signal is generated when the phase of the input signal leads the phase of the target clock signal.

23. (New) The apparatus of claim 21, wherein the second control signal is generated when the phase of the input signal lags the phase of the target clock signal.

24. (New) The apparatus of claim 21, wherein the second reference clock frequency is N times the frequency of the target clock signal and the specified range ranges from a positive number of $N/2$ to a negative number having an absolute value of $N/2$.

25. (New) The apparatus of claim 21 further comprising:
means for counting the cycle number of cycles of the first reference clock and resetting the cycle number after each N cycles of the first reference clock;
means for generating an enable signal when the cycle number of the first reference clock is equal to the phase adjusting value;
means for generating an impulse when receiving the enable signal;
means for outputting the target clock signal while receiving the impulse; and
means for inverting the target clock signal to feedback to the input.

26. (New) The apparatus of claim 21 being applied to an optical disc drive, the input signal being a wobble signal of an optical disc, the target clock signal being a corresponding wobble clock generated by the optical disc drive based on the wobble signal.
